

Introduction

The confluence of materials sciences and artificial intelligence (AI) has been heralding a surge of research on functional materials discovery and property predictions. Machine learning, as one of the most essential techniques in AI, has proved its superhuman ability in guiding chemical synthesis¹, enhancing computational chemistry², targeting the discovery of new catalysts³ and more. Despite its success in the field of materials discovery, complementary research in machine learning for materials characterization is still limited and primarily focuses on supervised deep learning models or direct adaptation of well-developed models to experimental datasets. Here, we present a machine learning framework that rapidly extracts and reports an interpretable hierarchy of complex structural motifs from atomically-resolved images⁴.

Key Challenges

1. I don't understand what my ML model is learning! **How to represent structural motifs with human-interpretable features?**

2. Unsupervised identification of motifs: **How to improve cluster separability?**

3. Can we generalize to different types of samples and modalities (e.g., AFM, STM, STEM, etc.)? **How to keep the framework flexible?**

4. How structural motifs are randomly placed? **How do they self-organize into hierarchies?**

Structural motif representations

Challenge 1

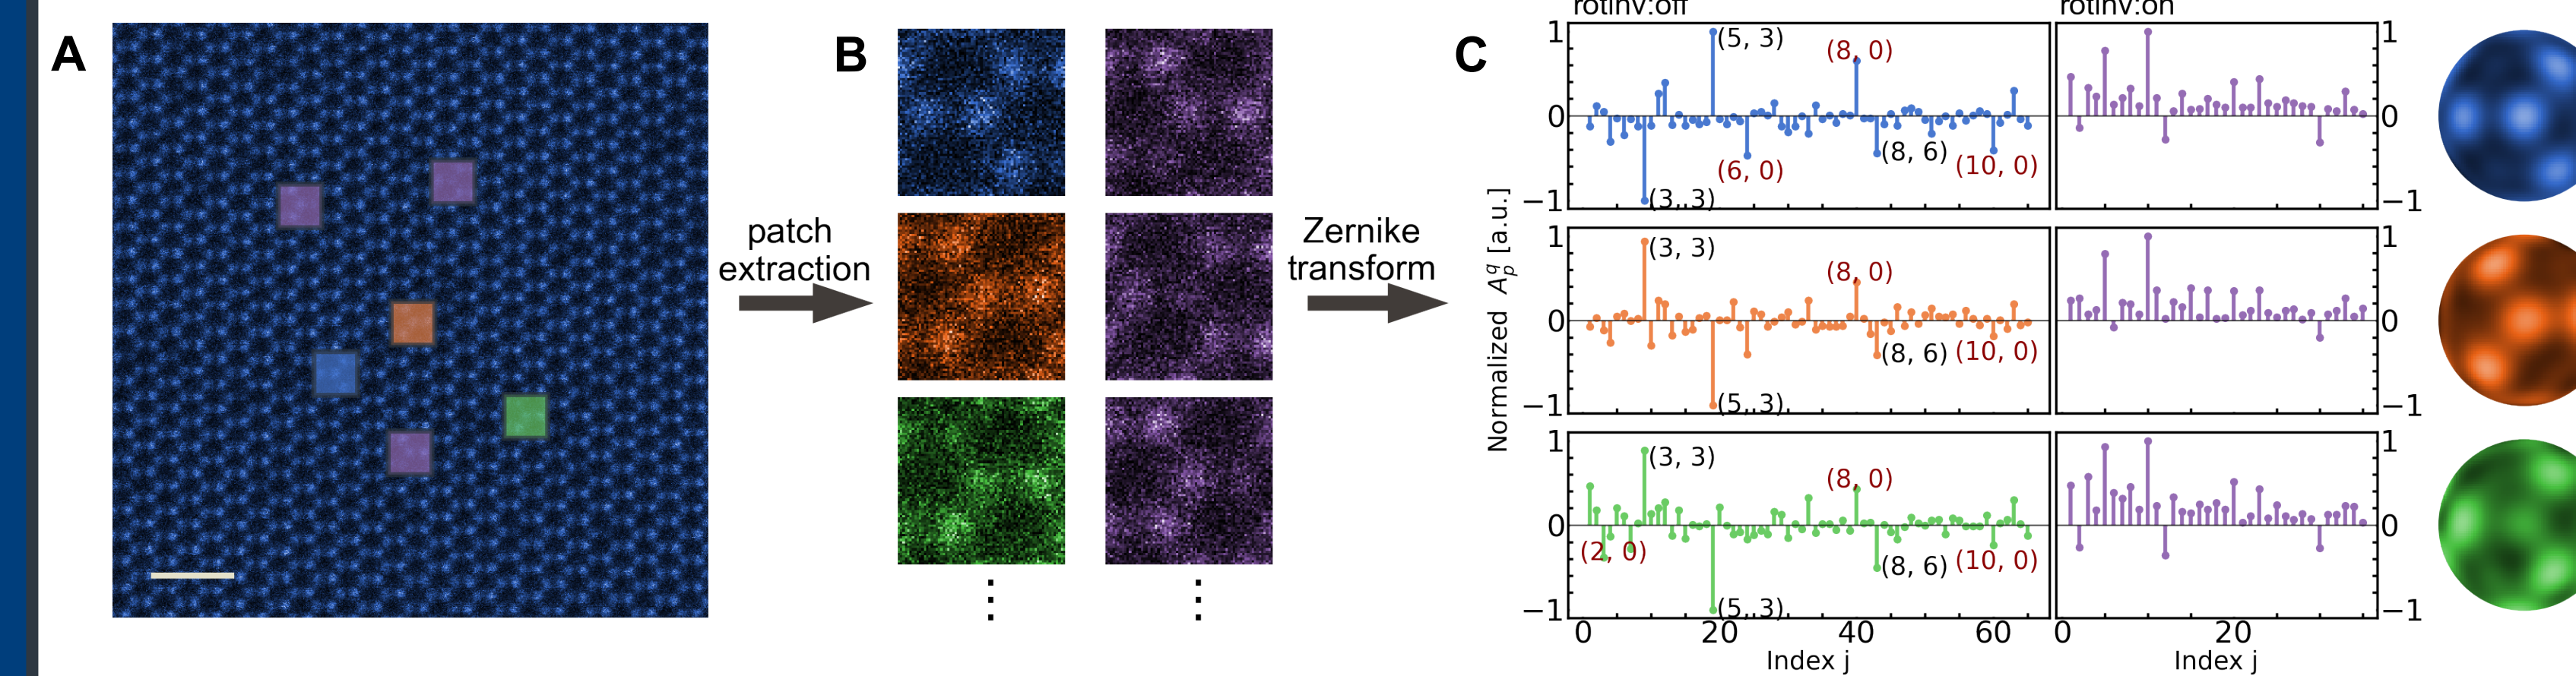

Fig. 1. Interpretable and flexible atomic structural motifs representation via Zernike polynomials (ZPs). (A) ADF-STEM image of monolayer MoSe₂ (scale bar: 0.5 nm). (B) Automatically extracting atom-centered image patches from panel (A). (C) Computing the Zernike features within the image patches in panel (B) either in their rotationally invariant representation (rotinv:on) or retaining rotation information (rotinv:off).

Two-Stage Force-relaxed clustering

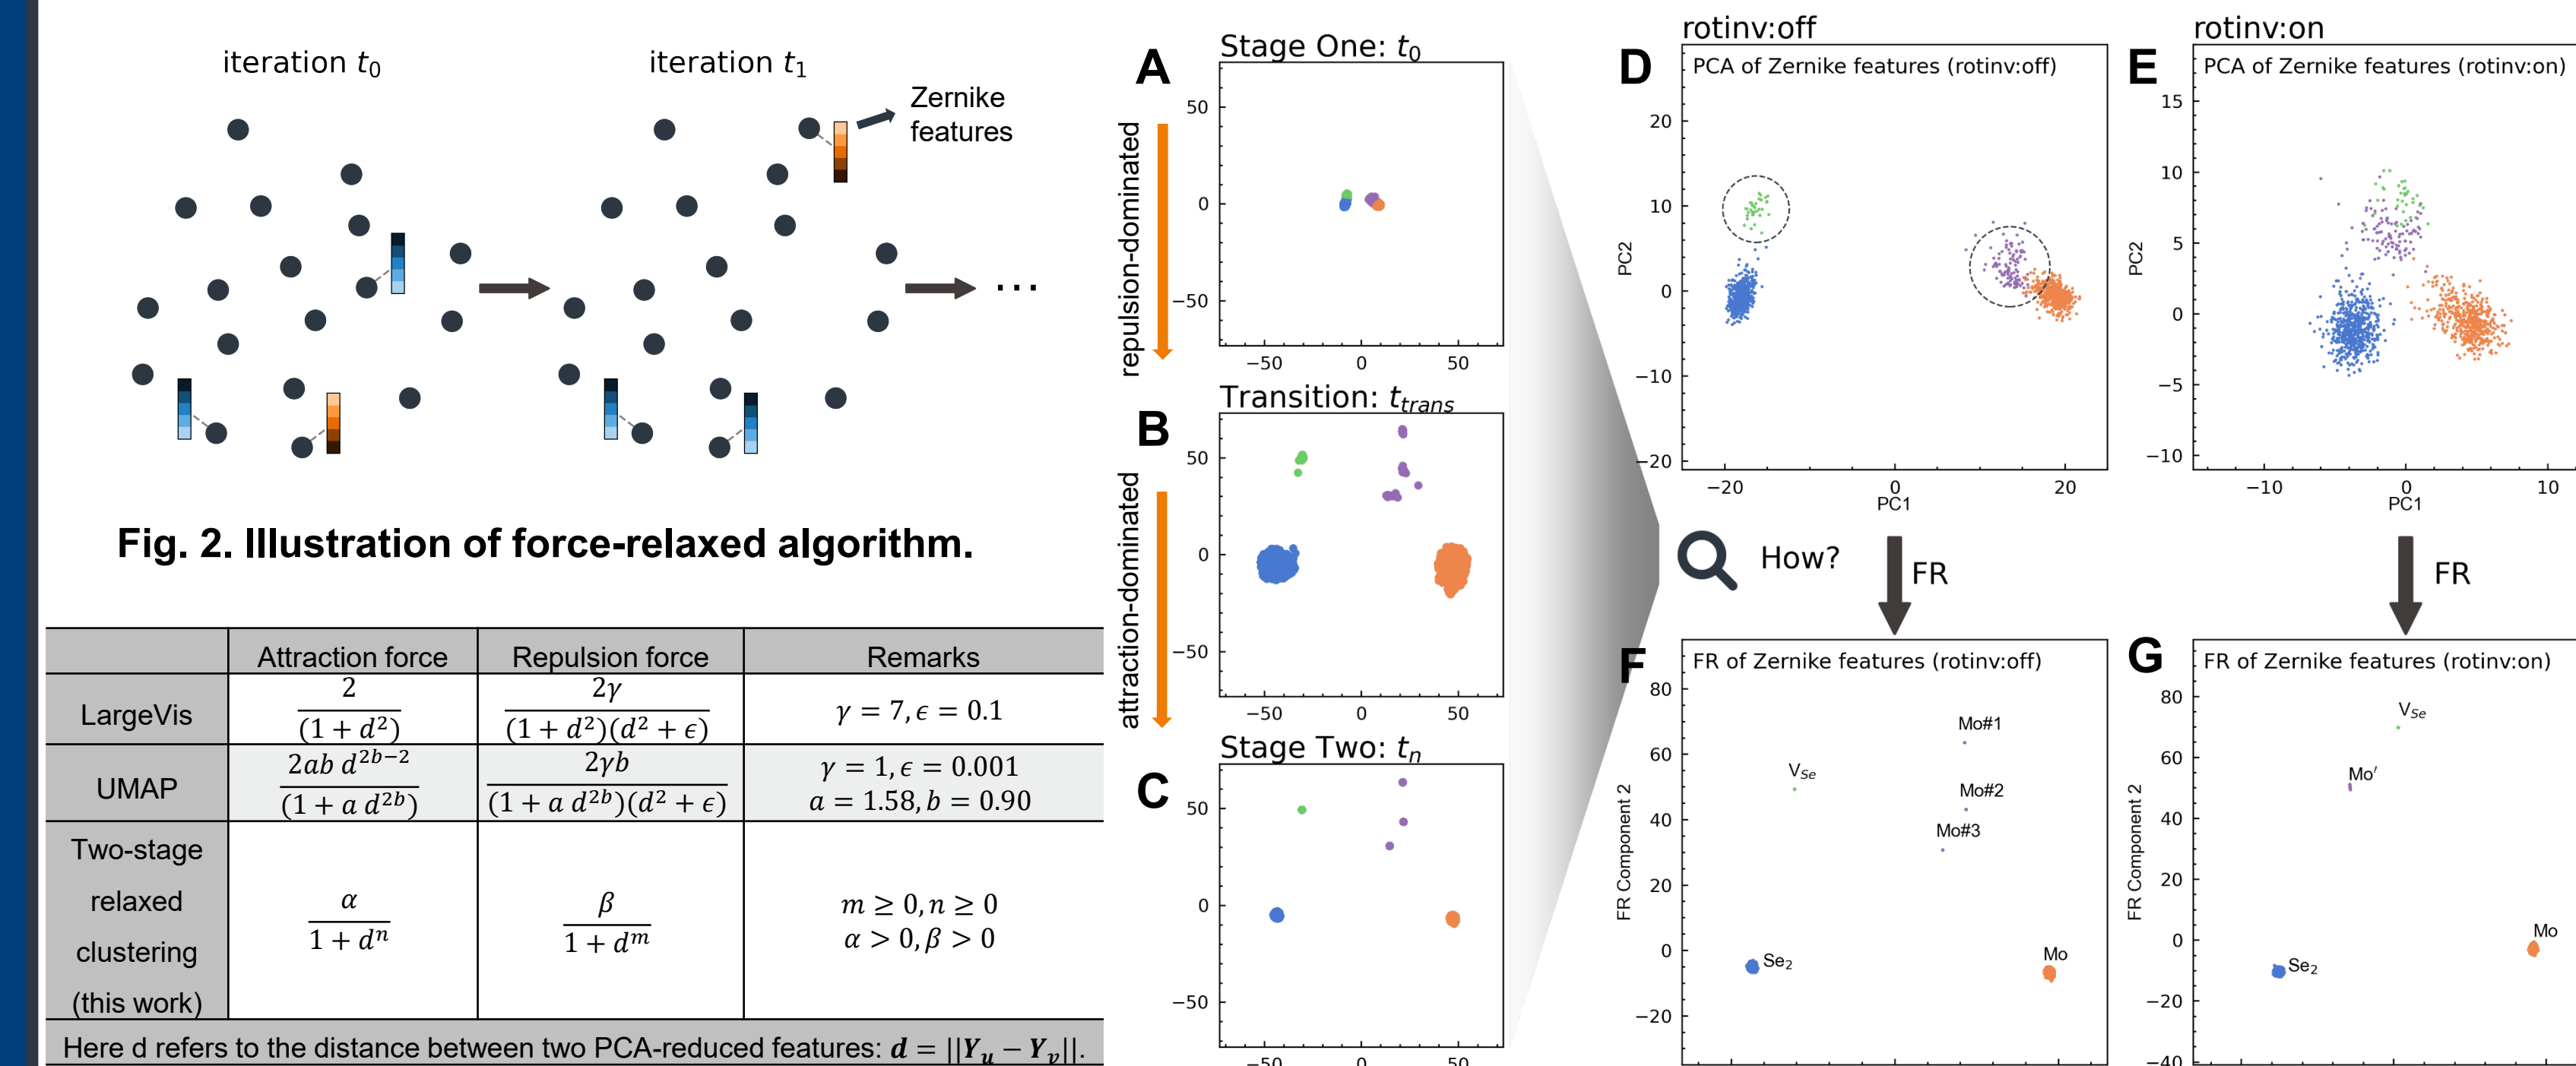

Table 1. A summary of force functions in different iterative clustering algorithms

	Attraction force	Repulsion force	Remarks
LargeVis	$\frac{2y}{(1+d^2)}$	$\frac{2y}{(1+d^2)(d^2+\epsilon)}$	$\gamma = 7, \epsilon = 0.1$
UMAP	$\frac{2ab d^{2b-2}}{(1+a d^{2b})}$	$\frac{2yb}{(1+a d^{2b})(d^2+\epsilon)}$	$\gamma = 1, \epsilon = 0.001$ $a = 1.58, b = 0.90$
Two-stage relaxed clustering (this work)	$\frac{\alpha}{1+d^n}$	$\frac{\beta}{1+d^m}$	$m \geq 0, n \geq 0$ $\alpha > 0, \beta > 0$

Here d refers to the distance between two PCA-reduced features: $d = \|Y_n - Y_m\|$

Here d refers to the distance between two PCA-reduced features: $d = \|Y_n - Y_m\|$

Challenge 2

Fig. 3. PCA and Force-relaxed (FR) layouts of Zernike features from monolayer MoSe₂ sample. From (A) to (B), repulsion-dominated stage. From (B) to (C), attraction-dominated stage. (D) and (E) project the patches' Zernike representations in their first two principal components. (F) Applying a force-relaxed clustering algorithm acting on these Zernike features automatically classifies them into different atomic structural motifs; (G) clustering on the rotationally invariant representations (rotinv:on) neatly groups features centered on Mo atoms together.

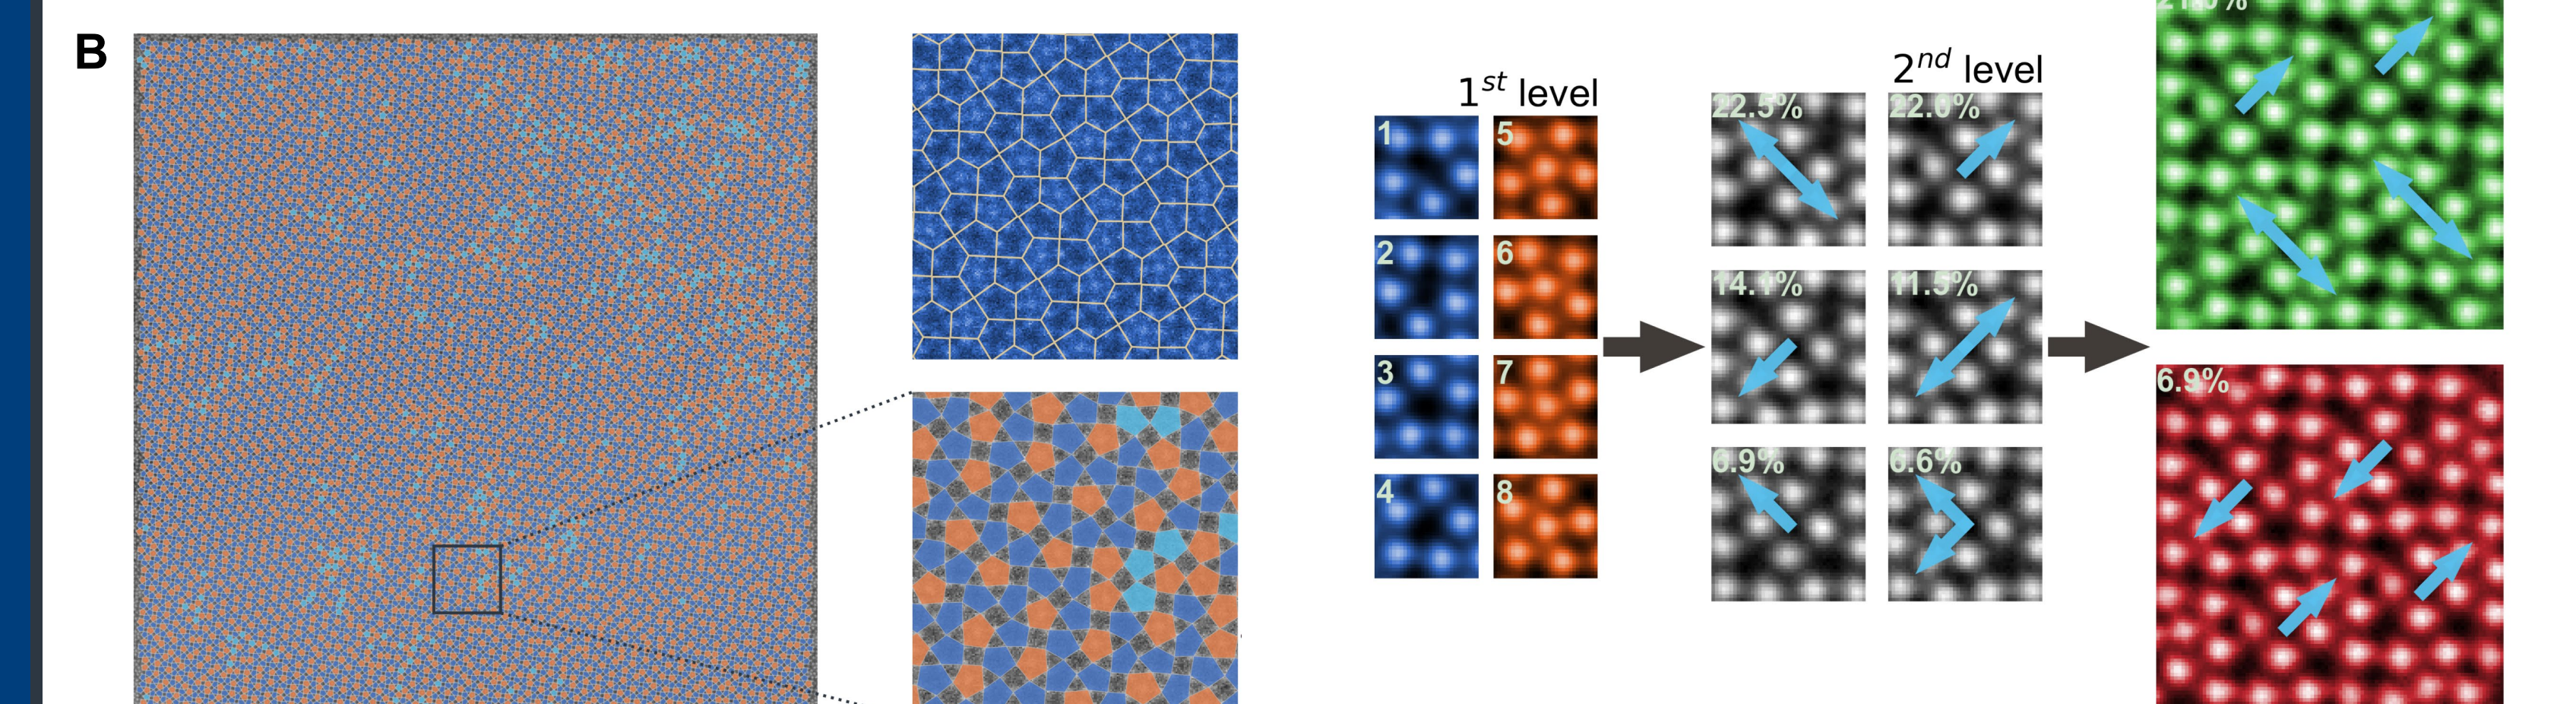

Combination of ZPs and FR gives more flexibility (Challenge 3)

Motif hierarchy in sample complexity spectrum

Simple motifs, simple hierarchy

Simple motifs, complex hierarchy

Complex motifs, "continuous hierarchy" becomes manifold

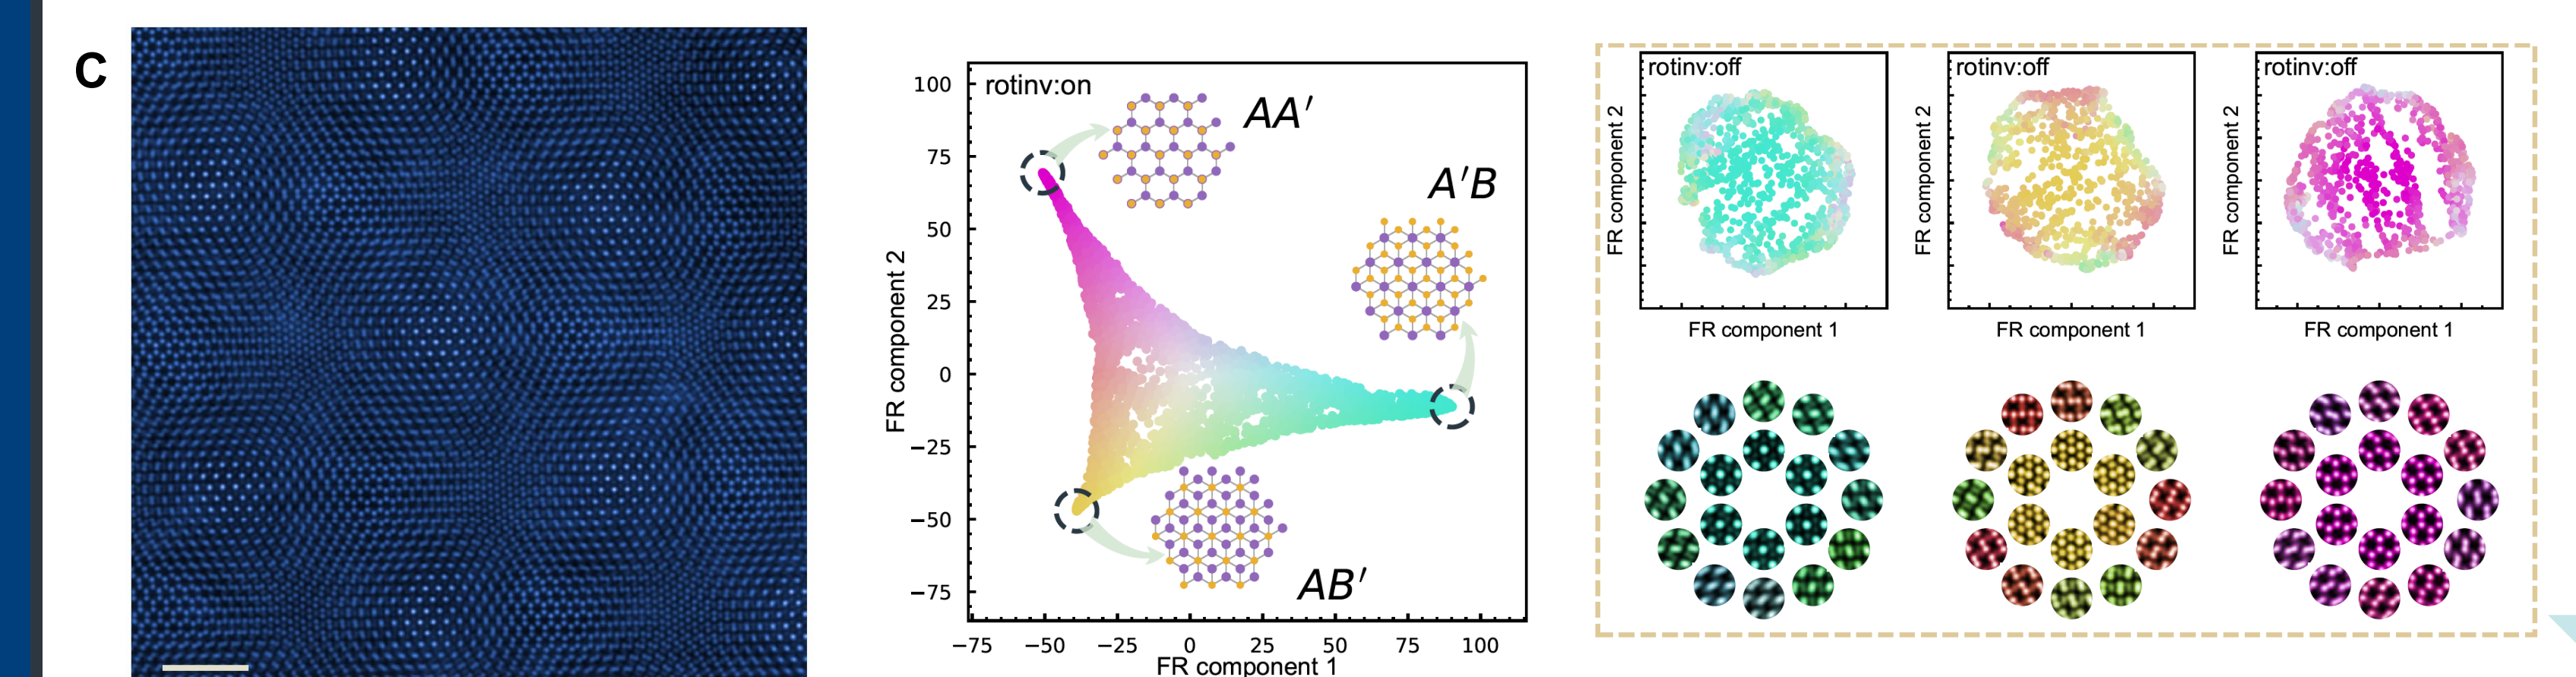

Fig. 4. Hierarchies of motifs in samples of increasing structural complexity. (A) Construction of hierarchy of *motif-cells* found in the monolayer MoSe₂ sample. (B) Hierarchy of motifs in polyoxometalate Mo-V-Te-Nb-oxide. (C) Structural motifs in twisted bilayer MoSe₂ form spatial hierarchy reflected by a continuous manifold.

Challenge 4

Conclusions

We have described a framework that exploits the spatial context between simple motifs to learn a hierarchical composition of higher-level motifs. The capability to algorithmically construct structural hierarchy from microscopy images without human supervision has the potential to alter how materials scientists characterize and interpret complex materials structures, usually not readily evident to human eyes, in areas like oxide thin films, metal halide perovskite, colloidal crystal.
